01.Indexed Arrays

Sunday, March 15, 2026 3:38 PM

Syntax: name = (elements) syntax to create an array

! when expanded like a normal variable ($ name) it will only provide the first element of the array

To get an element on a specific position ${name[n]}

${name[-1]} get last element → in bash you can index backwards

${name[idx]} where idx is a variable previously decl.

${name[*]} prints all elements but also 'rees' all elements as one → ! when you want a string

${name[@]} prints all elements but also properly brakes them as an array (e.g. for a loop)

! quotes " " + at sign @ to properly loop over the elements of an array

declare -a name =( ) to declare an array (not mandatory)

newarr = ("${ arr[@] }") to copy an array

newarr += (elements) add elements to the array

declare -p name shows all the attributes of the array

& bash has sparse arrays (you can have element [n] without having element [n-1]

"${ #array[@] }" length of the array

"${ #array[n] }" length of the string
